THE SYSTEM

Most trading agents predict one future. Seoul Shield compares the original order with a controlled alternative before capital moves. Gemini proposes; deterministic policy verifies; only an explicitly approved Paper path can execute.

VERIFIED ALPACA AND GEMINI

A live Alpaca Paper scan evaluated SPY, QQQ, AAPL, and NVDA. Gemini returned schema-validated candidate scores, selected AAPL with 85% bullish confidence, and produced input and output hashes. The account showed \$100,000 equity, Options Level 3, zero orders, and zero positions.

CONSERVATIVE RISK POLICY

With no verified historical IV series, the system did not invent an IV percentile. IV_HISTORY_UNAVAILABLE reduced the risk cap to 0.5% (\$500) and capped size at two contracts. Current IV, spread, OI, volume, quote age, and measured 5- and 15-minute returns remained explicit inputs.

TWO FUTURES

The original four-contract AAPL 330/335 bull call debit spread carried \$952 maximum loss and was blocked at \$452 over the conservative limit. The controlled two-contract future carried \$476 maximum loss, or 0.476% of equity, and reached Paper Preview only.

THE SAFETY EVENT

Before execution, AAPL changed from bullish to bearish across the measured 5- and 15-minute windows. The bullish strategy became directionally incompatible. Seoul Shield invalidated the preview and kept the broker latch closed.
